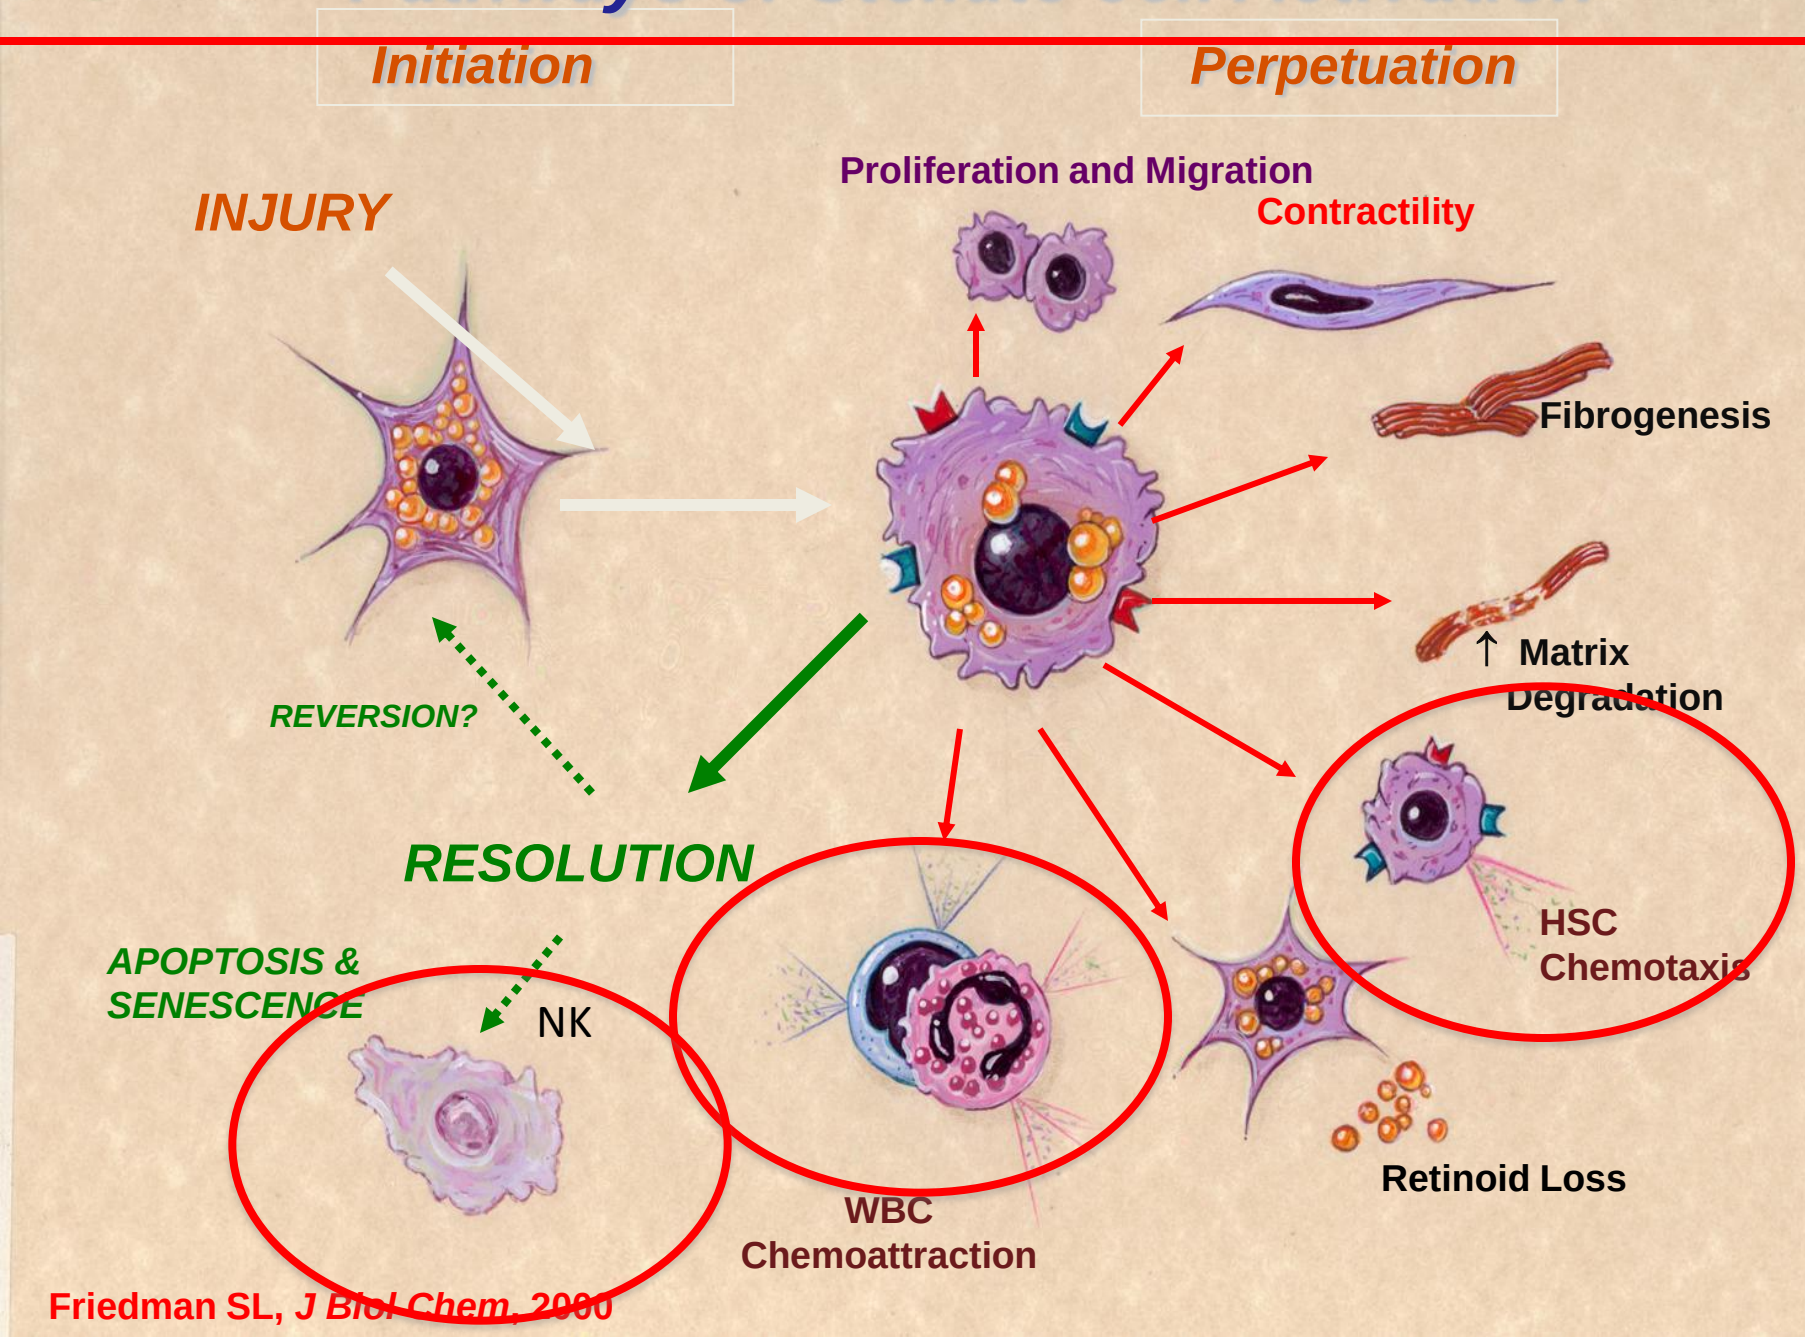
Pathways of Stellate cell Activation



Friedman SL, *J Biol Chem*, 2000

CCR5 and liver fibrosis

Hepatic fibrosis develops as a response to chronic liver injury and almost exclusively occurs in a pro-inflammatory environment.
(Friedman Sl. et al. Physiol rev; 2008)

However, the role of inflammatory mediators in fibrogenic responses of the liver is only poorly understood

Hepatic stellate cells (HSCs), the main fibrogenic cell population of the liver, are a key player in the fibrotic response. (Friedman Sl. et al. Physiol rev; 2008)

CCR5 is highly expressed on HSCs membrane, promotes their migration to the site of injury, leads the recruitment of other cell types including Kupffer cells and subsequent HSCs activation. *(Schwabe RF et al.,2003; Ekiro S. etal. J Clin Invest,2009)*

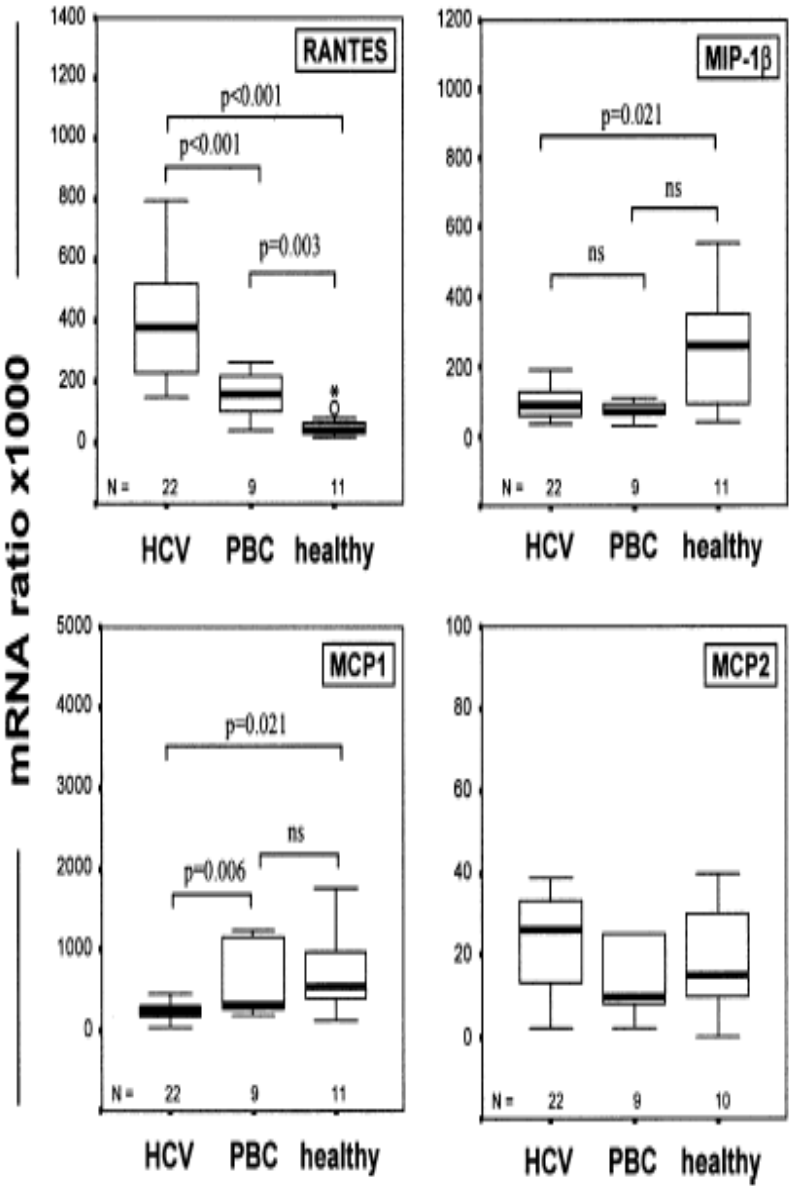
Semiquantitative analysis of intrahepatic CC-chemokine mRNAs in chronic hepatitis C*

Hans Dieter Nischalke[1], Jacob Nattermann[1], Hans-Peter Fischer[2], Tilman Sauerbruch[1], Ulrich Spengler[1] and Franz Ludwig Dumoulin[CA]

Higher intrahepatic RANTES mRNA levels in chronic hepatitis C.

enhanced expression of RANTES mRNA correlates to CD8 gene expression and to the extent of liver damage, suggesting that a release of proinflammatory cytokines by activated T cells contributes to immunemediated liver damage in hepatitis C



Mediators of Inflammation
Volume 13 (2004), Issue 5-6, Pages 357-359

Antagonism of the chemokine Ccl5 ameliorates experimental liver fibrosis in mice

Marie-Luise Berres,[1] Rory R. Koenen,[2] Anna Rueland,[1] Mirko Moreno Zaldivar,[1] Daniel Heinrichs,[1] Hacer Sahin,[1] Petra Schmitz,[1] Konrad L. Streetz,[1] Thomas Berg,[3] Nikolaus Gassler,[4] Ralf Weiskirchen,[5] Amanda Proudfoot,[6] Christian Weber,[2] Christian Trautwein,[1] and Hermann E. Wasmuth[1]

we identify the chemokine CCL5 (also known as RANTES), which is induced in murine and human liver after injury, as a central mediator of this interaction.

First, we showed in patients with liver fibrosis that *CCL5* haplotypes and intrahepatic *CCL5* mRNA expression were associated with severe liver fibrosis.

Consistent with this, we detected *Ccl5* mRNA and CCL5 protein in 2 mouse models of liver fibrosis, induced by either injection of carbon tetrachloride (CCl4) or feeding on a methionine and choline–deficient (MCD) diet. In these models,

***Ccl5*–/– mice exhibited decreased hepatic fibrosis, with reduced stellate cell activation and immune cell infiltration.**

Transplantation of *Ccl5*-deficient bone marrow into WT recipients attenuated liver fibrosis, identifying infiltrating hematopoietic cells as the main source of Ccl5.

We then showed that treatment with the CCL5 receptor antagonist Met-CCL5 inhibited cultured stellate cell migration, proliferation, and chemokine and collagen secretion. Importantly, in vivo administration of Met-CCL5 greatly ameliorated liver fibrosis in mice and was able to accelerate fibrosis regression.

Our results define a successful therapeutic approach to reduce experimental liver fibrosis by antagonizing Ccl5 receptors.

Anti-retroviral drugs do not facilitate hepatitis C virus (HCV) infection *in vitro*

Lisa Sandmann [a], Matthew Wilson [a], David Back [b], Heiner Wedemeyer [a], Michael P. Manns [a], Eike Steinmann [c], Thomas Pietschmann [c], Thomas von Hahn [a,d], Sandra Ciesek [a,c,*]

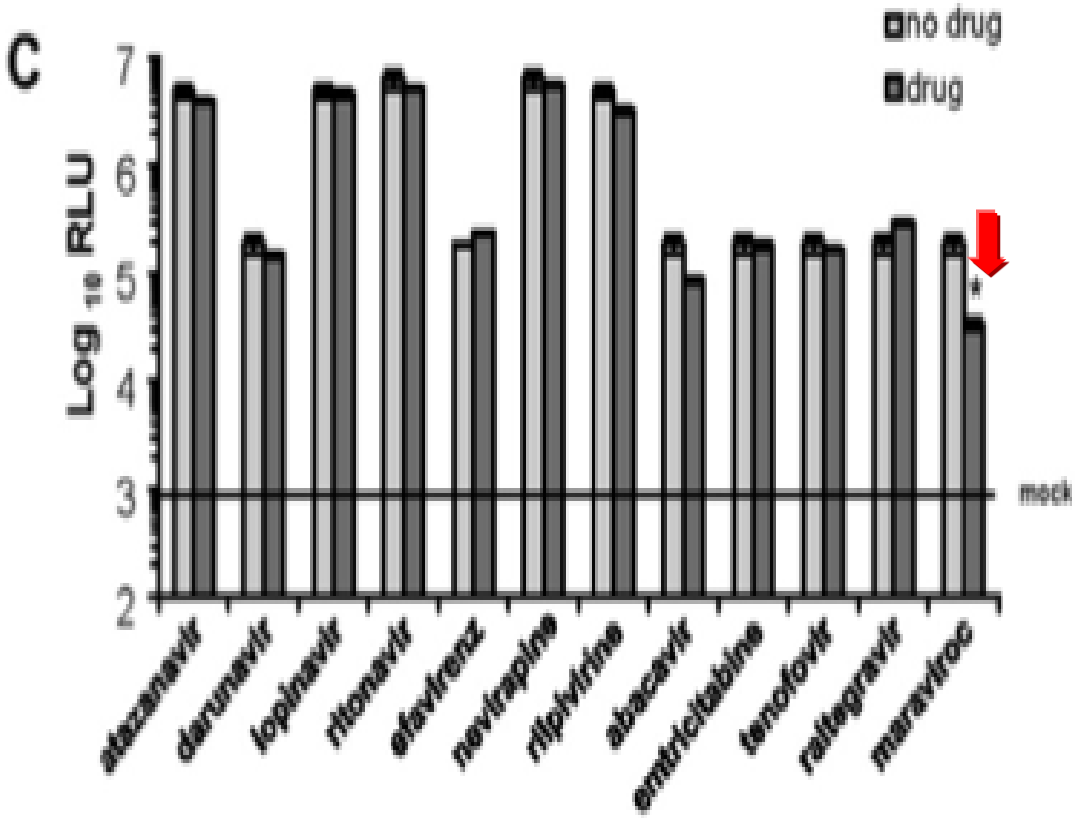
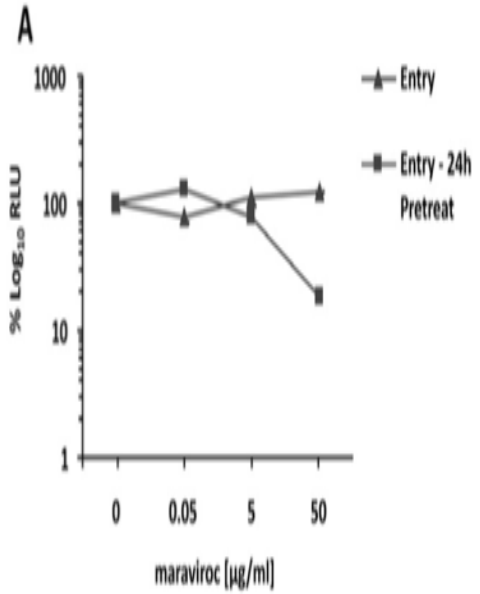
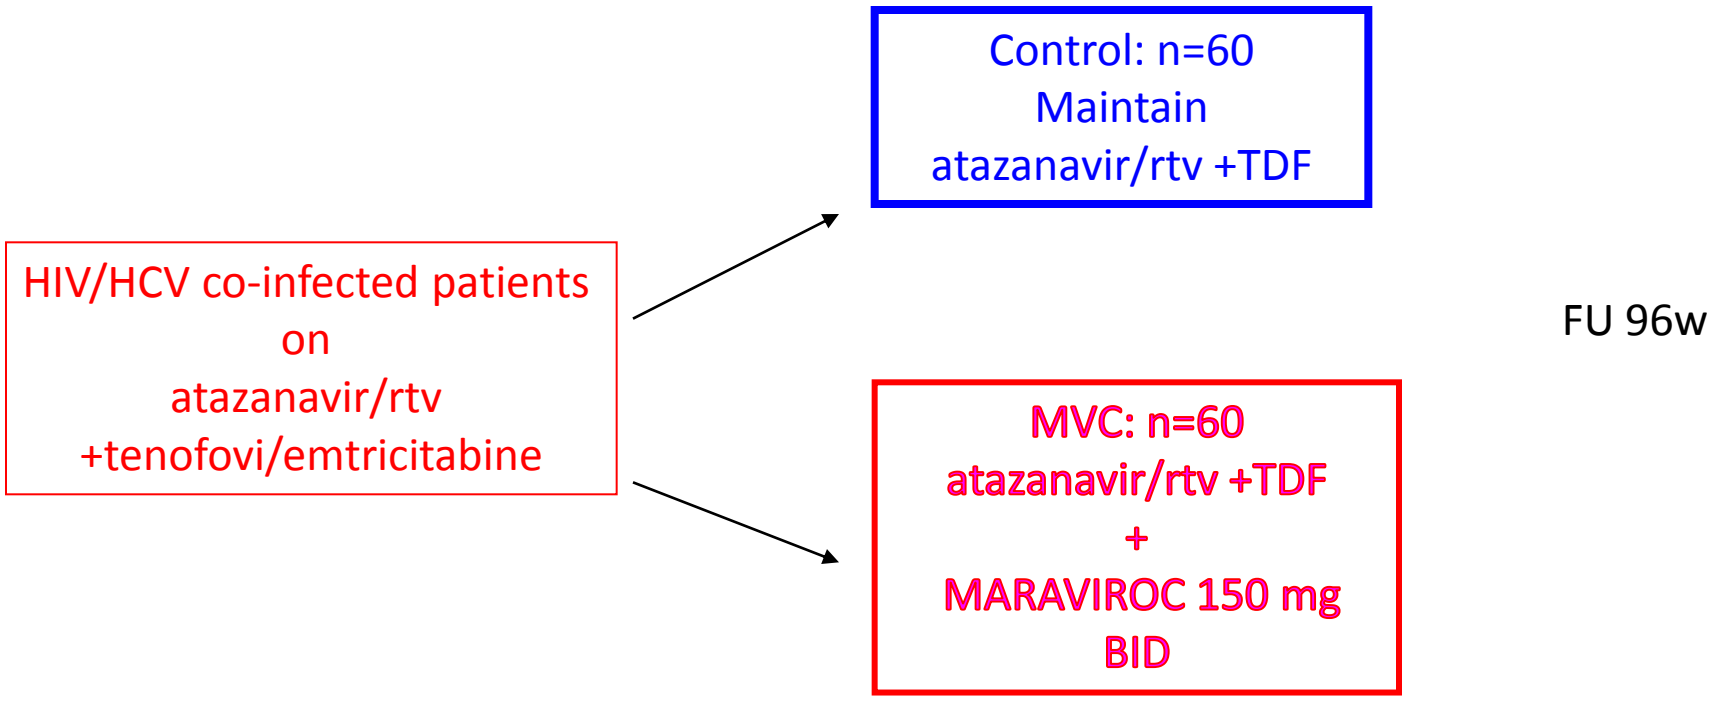
While most of the drugs did not have an effect on HCV entry even after 24 h pre-treatment, pre-treatment with the CCR5 receptor antagonist maraviroc showed an 8 to 10-fold reduction of HCVcc entry .





STUDY DESIGN

- Phase III, proof of concept, prospective, open label, randomized, controlled trial
- HIV/HCV co-infected subject with undectable HIV-RNA (< 50 copies/ml - bDNA) taking HAART based on Atazanavir 300 /ritonavir 100 qd plus Truvada®
- Patients will be screened and randomized 1:1 in two arm:



* Safety analysis of the intervention was planned on the first 60 patients enrolled before continuing enrolment in the study

KEY INCLUSION CRITERIA

•Patient with HIV-1/HCV (HCV-RNA detectable at quantitative analysis) co-infection

•Currently receiving a PI based HAART for at least 24 week based on Tenofovir/emtricitabine + Atazanavir 300mg/ritonavir 100 mg

•HIV-RNA < 50 copies/ml confirmed in two consecutive examination in the previous 3 months

•Without cirrhosis (based on hystological or echographycal or clinical signs)

KEY EXCLUSION CRITERIA

•Alcool intake >2 glasses daily

•Previous us of anti HCV treatment

•Need to use PegIFN/RBV in the next two years

•Child Pugh liver function classification > A 6

•HBsAg+ co-infection

•Grade ¾ laboratory abnormalities defined by DAIDS grading table

•Co-medication with statins or hypoglycaemic drugs

Primary end point

Proportion of patients with or without change in fibrosis stage at week 48 and at week 96 determined with transient Elastometry- Fibroscan® *(Castera L. et al, Gastroenterology; 2005)* *and Fibrotest* ®(Halfon P. et al. Am J Gastroenterol,2006)

Stage	Fibroscan : Liver Stiffness Kpa	Fibrotest
I (F0-1)	<7,1	0,22-0,27
II (F2)	7,1-9,4	0,49-0,58
III(F3)	9,5-12,4	0,59-0,72
IV(F4)	≥12,5	0,75-1

LIVER STIFFNESS MEASUREMENT:FIBROSCAN®

An officially trained physician performed
Livers Siffness measurement using Fibroscan® on fasting patients
The median value of 10 successful measurement
and success rate (defined as ratio of successful measurement) of at least 60% were only considered for evaluation

Secondary end point

1) Proportion of patient with reduction of ≥50 ng/ml of Hyaluronic acid plasma concentration from BL at week 24,48, 96

2) Change from baseline at week 24,48,96 of:

- AST/ALT, ALP, GGT, Bil tot,PLT, ALB (direct and indirect)
- Quantitative HCV-RNA ,HIV-RNA
- PCR, Alfa 1 antitripsin, fibrinogen,
- Total Cholesterol, LDL, HDL, triglycerides, HOMA score
- T CD4+ cell count and CD8+T cell count

Antivir Ther. 2011 ; 16(5): 667–675. doi:10.3851/IMP1815.

Hyaluronic Acid Levels Predict Increased Risk of Non-AIDS Death in Hepatitis Coinfected Persons Interrupting Antiretroviral Therapy in the SMART Study

Lars Peters[1], Jacqueline Neuhaus[2], Amanda Mocroft[3], Vincent Soriano[4], Jürgen Rockstroh[5], Gregory Dore[6], Massimo Puoti[7], Ellen Tedaldi[8], Bonaventura Clotet[9], Bernd Kupfer[5], Jens D Lundgren[1,10], and Marina B Klein[11] for the INSIGHT SMART Study Group

Probaility of NON AIDS death according with HA at BL

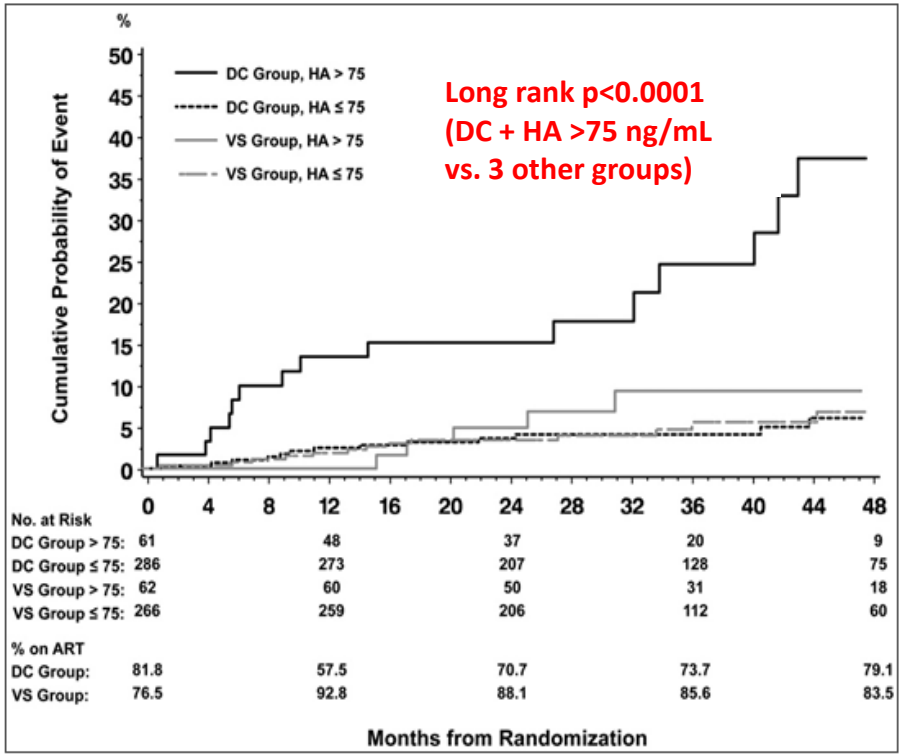


Figure 1
Cumulative probability of non-AIDS death according to randomization group and baseline hyaluronic acid (HA) (ng/mL) level in coinfected participants

Probability of Liver related death according with HA at BL

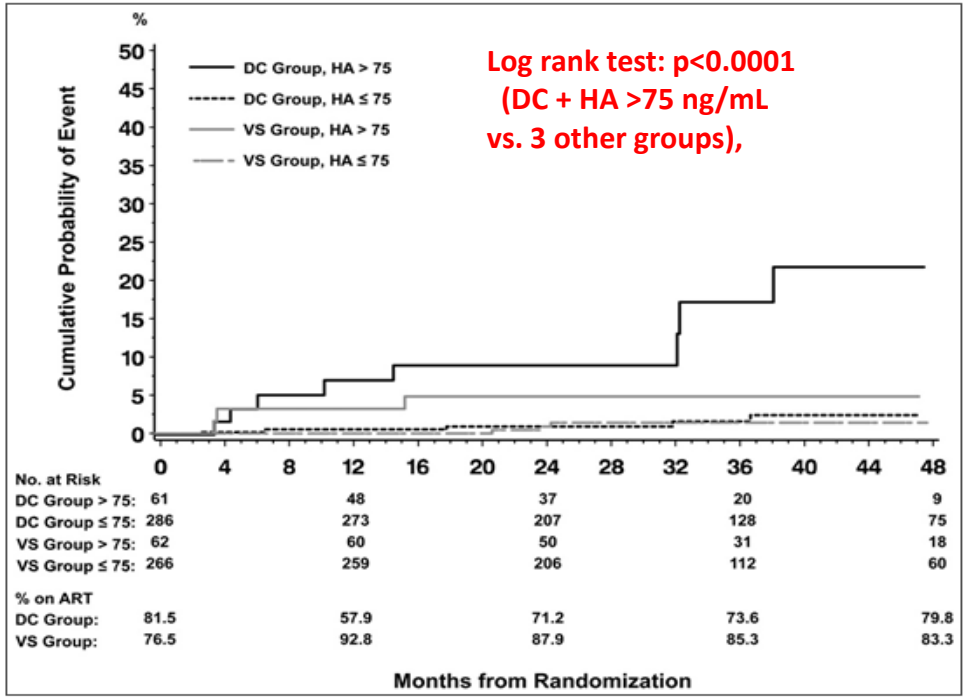

Figure 2
Cumulative probability of liver-related death or development of cirrhosis according to randomization group and baseline hyaluronic acid (HA) (ng/mL) level in coinfected participants

DC: drug conservation,
VS: viral suppression

Hyaluronic acid measurement

HA was measured in stored plasma samples at baseline and at 24,48 and 96 week using a commmecial ELISA-assay (Echelon Biosciences Inc®) with a HA range in a healthy population between 50–120 ng/mL.

Planned preliminary 96 week analysis on first 60 patients enrolled : patient disposition

Maraviroc in patients with chronich liver diseases

Several HIV/HCV co-infected patients shall remain non eligible to receiving peginterferon/ribavirin and may not have or even anti HCV treatment option in the next future

Many patient will have a cirrhosis when IFN free regimens will be achievable and, also after HCV eradication, will remain at risk for HCC development (Berenguer ,2013)

A liver friendly antiretroviral therapy could be the only barrier, to the rapidly progressive liver disease

Maraviroc have a large evidence of good efficacy and safety in HIV/HCV co-infected patients and may represent a reasonable choice in this fragile population
